

The hierarchy of phonetic features in printed syllables matching, in adult skilled readers, normally developing young readers and dyslexic children

Nathalie Bedoin & Sonia Krifi

Laboratoire EMC / DDL, Université Lyon 2

Syllable matching task :

choice between two phonetic features categories

Experiments designed to investigate the hierarchical organization of cognitive (but implicate) knowledge of 3 categories of phonetic features :

Voicing

Place of articulation

Manner of articulation

- 3 printed CV, the vowel was always /a/
- The target syllable was to be matched with one of two printed CV, according to intuitively estimated acoustic similarity

- Experiment 1 : Manner / Voicing
- Experiment 2 : Manner / Place
- Experiment 3 : Voicing / Place

Example (Voicing-Manner)

ja

ka

ba
+

Participants

- 24 adults, normal reading level, without academic knowledge in linguistics
- 10 children with normal reading level, 2^d graders (CE1)
- 20 dyslexic children (Debrousse Hospital, Lyon)

12 dyslexic children :

- 6 had phonological deficit

Chronological age = 11 years 10 months

Lexical level = 7 years 10 mois

Reading retardation

= 4 years

- 6 had no obvious phonological deficit

Chronological age = 12 years

Lexical level = 8 years 1 month

Reading retardation

= 3 years 11 months

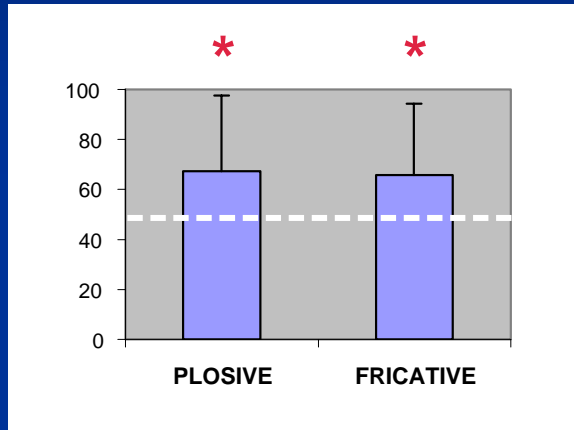

Each child is paired with another one for age and lexical level

MANNER or PLACE ?

Adults

% of Manner matching

target

2^d graders

target

Dyslexic children with phonological deficit

target

Growing preference for Manner (versus place),
from dyslexic group, to 2d graders, to adults

MANNER or VOICING ?

Adults

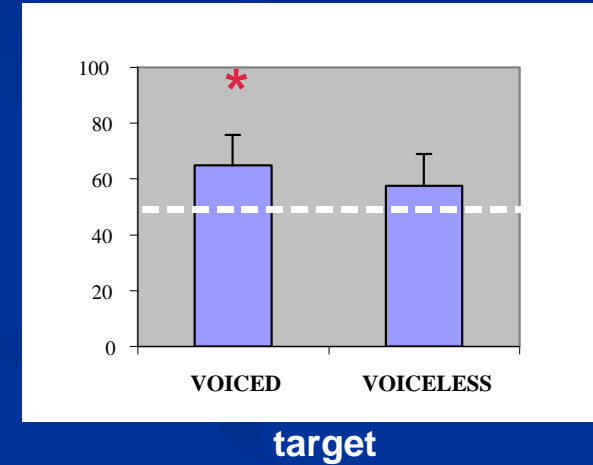

% of Manner matching

2^d graders

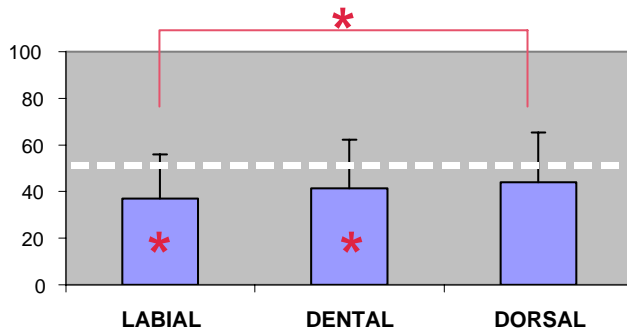

Dyslexic children with phonological deficit

- Young normal readers prefer Voicing to Manner, contrary to adults
- Dyslexic children are not similar to 2^d graders (not only a reading retardation, but a qualitative difference)
- Opposite modulating effect of the Voicing of the target upon the choice between Manner and Voicing

% Voicing matching

VOICING or PLACE ?

Adult skilled readers preferred Place for front consonants

2d graders have no preference for place

Dyslexic children prefer Place... but only for back consonants

Conclusion

- **Adult skilled readers** : a hierarchical organization for phonetic features categories in this implicit task

Prominent status for **Manner**

(compared with Place and with Voicing)

A slight role of Voicing similarity, as a modulator effect on Manner categorization

Preference for Place, rather than Voicing similarity, only for front consonants :

- visual influence (lip reading) (?)

- influence of articulatory properties (front-back) (?)

- influence of acoustical properties (?)

Conclusion (2)

- **Dyslexic children without obvious phonological deficit :**

➡ No preference for any category of phonetic features

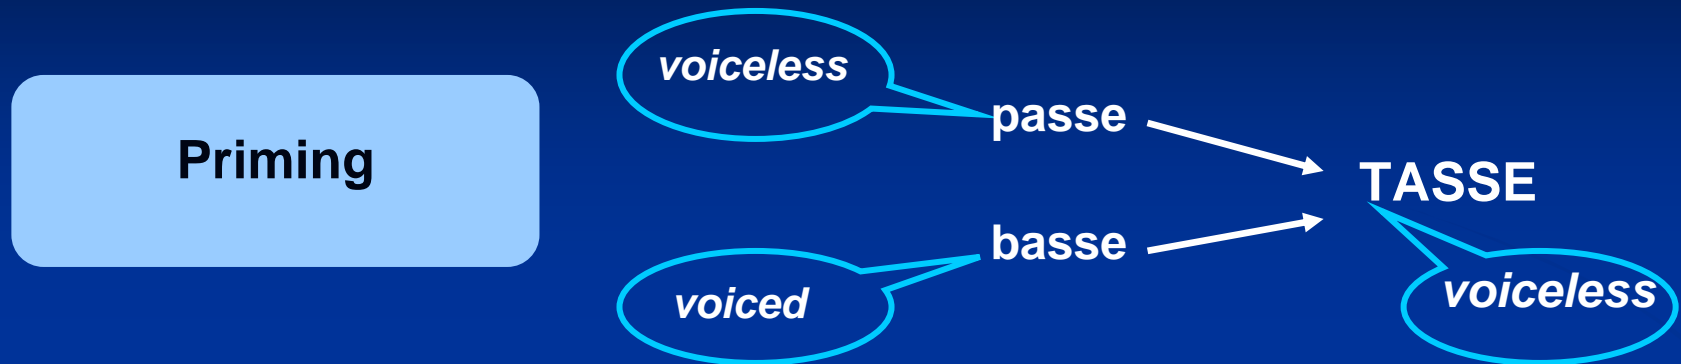

- **Dyslexic children with phonological deficit :**

➡ ➤ Do not respond at random

➤ They may use phonetical rules as a basis for phonemic knowledge organization

➤ But these rules seem different from those of adult skilled readers and normal reading children paired in reading level

Voicing similarity decreases performances on the 2d stimulus in lexical decision

Bedoin (1998)

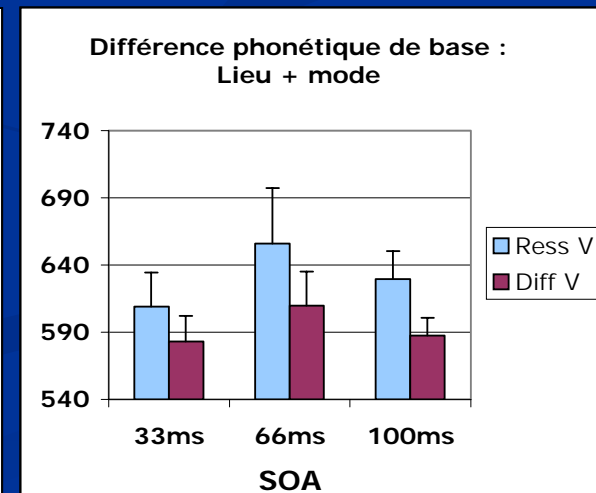

CONSTANT EFFECT :

- whatever the SOA :
 - SOA 33 ms $F_1(1,46)=13.15$; $p=.0007$, $F_2(1,10)=5.99$; $p=.028$
 - SOA 66 ms $F_1(1,22)=7.505$; $p=.012$, $F_2(1,10)=5.98$; $p=.0283$
 - SOA 100 ms $F_1(1,22)=13.715$; $p=.0012$, $F_2(1,10)=2.501$; $p=.136$
- whatever the prime lexicality : pseudoword as the prime
 - effect with pseudo-words, $F_1(1,26)=5.094$; $p=.03$, $F_2(1,13)=3.917$; $p=.06$
- whatever frequency difference between prime and target
- whatever the other phonetic difference between prime and target

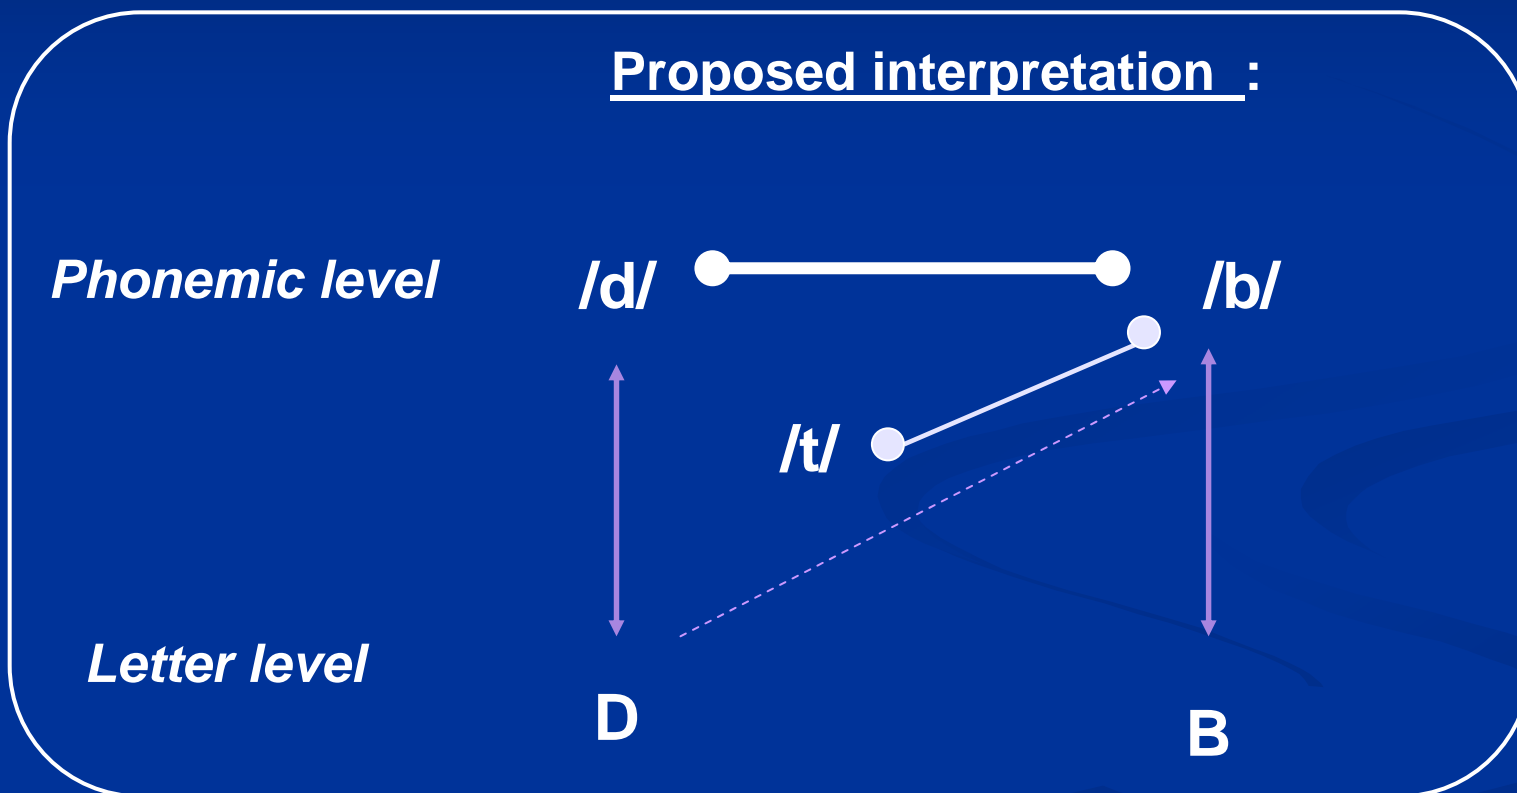

Place and Manner

Place

Manner

- The effect may be due to the organization of phonemic knowledge.
- Inhibitory relations are supposed between phonemic detectors, according to the number of shared phonetic features

To test this hypothesis : priming and backward masking experiments

SOA = 33 ms

Backward masking : recall of the 1st stimulus

target *mask*
(Ress) ZÉVUT
début
(Diff) SÉFUT

$F1(1,34)=8.865; p=.013$

$F2(1,22)=5.823; p=.0246$

Priming : lexical decision on the 2d stimulus

prime *target*
(Ress) zévut
DÉBUT
(Diff) séfut

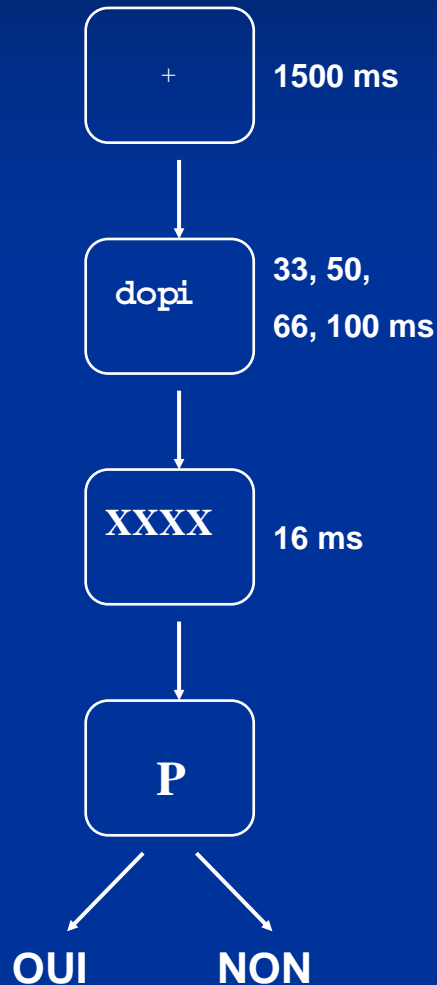

$F1(1,34)=8.025; p=.007$

$F2(1,22)=8.269; p=.009$

VOICING SIMILARITY :

- decreased performances for the 2^d stimulus,
- increased performances for the 1st stimulus

Both effects are replicated with voicing similarity manipulated within one single CVCV stimulus

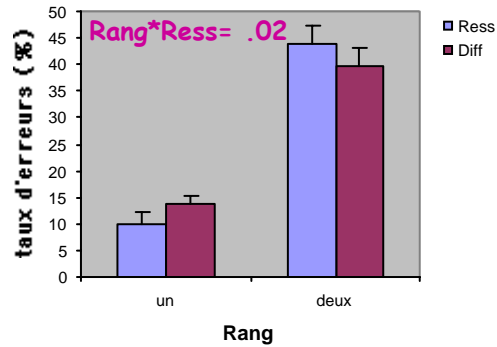

Letter detection task

Voicing similarity

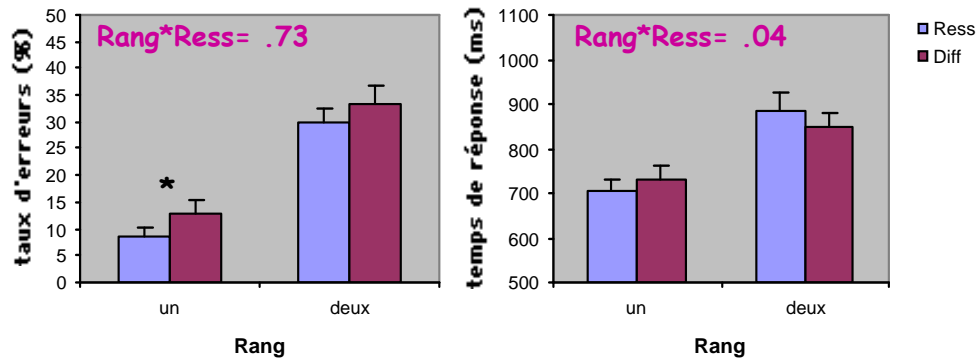

- decreased performances for C2
- increased performances for C1

Results in adults

Presentation = 33 ms

Presentation = 50 ms

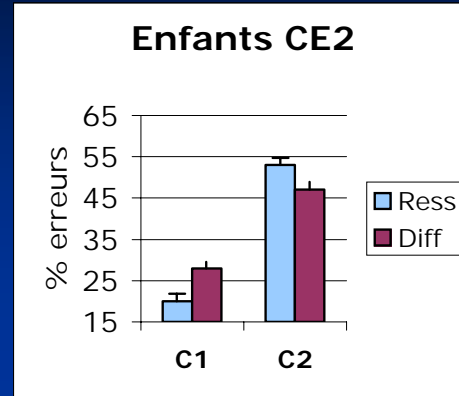

Presentation = 66 ms

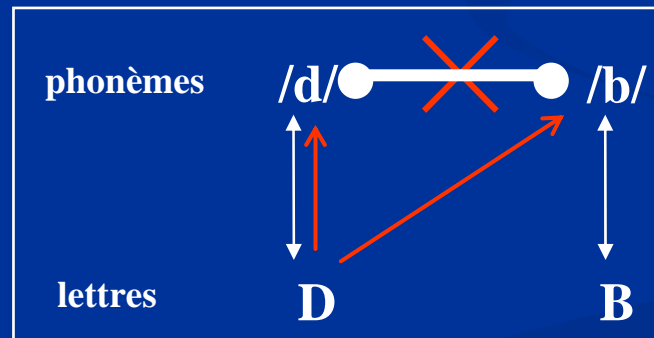

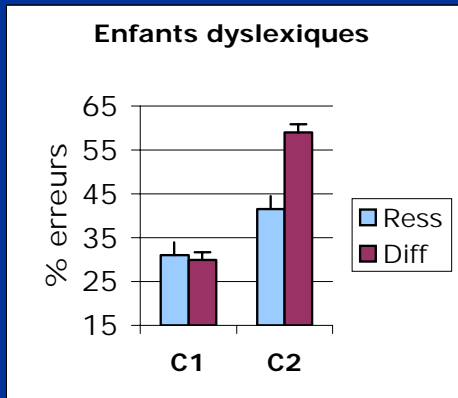

Presentation = 100 ms

→ no effect

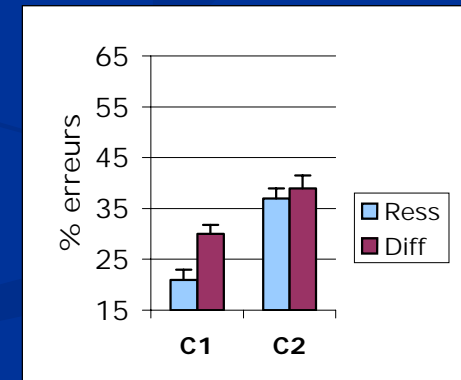

Results in normal reading children (presentation = 85 ms)

Results in dyslexic children

After an intensive audio-visual training about voicing :

(Krifi, Bedoin & Mériqot, 2003)

Voicing similarity effects (benefit for C1, cost for C2) in a syllable recalling test

Procedure :

Results :

Syllable rank X Voicing similarity,

$F(1, 23) = 41.78, p < .0001$

➤ Voicing similarity improves C1 processing

$F(1, 23) = 49.56, p < .0001$

➤ Voicing similarity impaired C2 processing

$F(1, 23) = 4.42, p < .047$

The role of other phonetic categories in priming

→ 6 experiments tested the role of Manner and Place similarity between two stimuli (lexical decision was made on the second stimulus)

Prime and target differed in voicing

- Experiment 7 (SOA = 100 ms)
- Experiment 8 (SOA = 66 ms)
- Experiment 9 (SOA = 33 ms)

Prime and target did not differ in voicing

- Experiment 10 (SOA = 100 ms)
- Experiment 11 (SOA = 66 ms)
- Experiment 12 (SOA = 33 ms)

33 ms

Expé. 9

Manner similarity increases performances

66 ms

Expé. 8

Place similarity decreases performances

100 ms

Expé. 7

Place similarity decreases performances

No difference in voicing

Expé. 12

Manner similarity

And

Place similarity increases performances

Expé. 11

Manner similarity decreased performances

Expé. 10

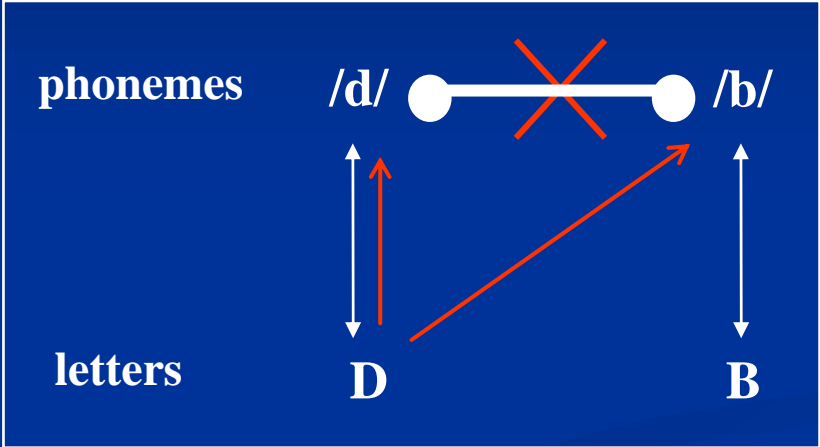

Place similarity and Manner similarity

creased response accuracy

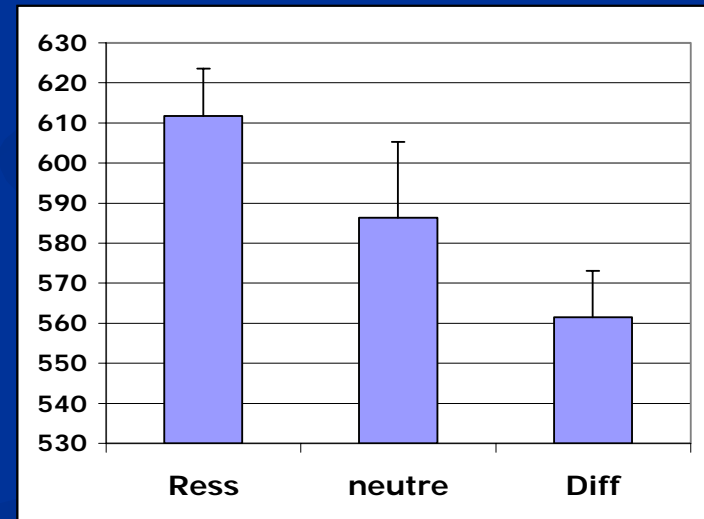

Expérience avec un essai de condition « neutre »

Chaque mot cible (e.g., PEINE) est précédé de :

- amorce qui diffère sur un trait (Lieu ou Mode) (teine)
- amorce qui diffère sur un trait (Lieu ou Mode) + sur le Voisement (deine)
- amorce sans phonème en commun et commençant par une voyelle ou une consonne liquide (aurul)

Résultats :

- effet du facteur condition,
 $F(2, 66) = 3.72, p < .03$
- différence entre les 2 conditions avec ressemblance ou différence de voisement, $F(1, 66) = 7.40, p < .01$

Effet négatif de ressemblance infra-phonémique sur le traitement du 2ème stimulus, dans d'autres travaux :

- Production de parole, (Rogers & Storkel, 1998)
- Perception de parole, (Goldinger, Luce, Pisoni and Marcario, 1992)

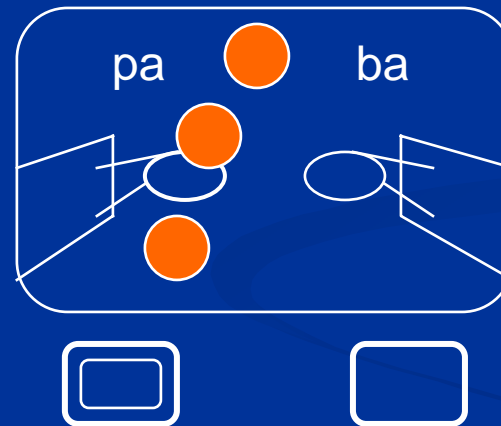

Deux propositions d'interprétation :

- **Effet de compétition** : la ressemblance faciliterait le traitement du 2ème stimulus qui, par effet de backward masking, restaurerait les traitements auparavant effectués sur le 1er stimulus (parce qu'il lui ressemble) --> renforcement de l'identification du 1er stimulus --> compétition entre les 2 stimuli

➔ Prédiction : le 1er et le 2ème stimulus devraient être moins bien identifiés

Entraînement audio-visuel intensif, portant sur les six oppositions de Voisement

3 sessions de 15 minutes par jour, 4 jours par semaine, pendant 3 semaines

Danon-Boileau &
Barbier, 2000

- 18 enfants répartis en deux groupes:
 - groupe A: bénéficiant de l'entraînement
 - groupe B: sans entraînement

Enfants dyslexiques
avant entraînement

Enfants dyslexiques
après entraînement
sur voisement

Enfants dyslexiques
après entraînement
sur vocabulaire
